Low-slope roofing trends in commercial buildings

13/03/2024

The low-slope roofing market is poised to take off, according to many experts. This type of roof is either almost completely flat or features a slight pitch, just enough to allow water to drain. It is referred to as a low-slope roof because the roof rises less than three inches vertically for every horizontal foot. However, many people remain unaware of this roofing option, as it doesn't get much fanfare.

Low-slope roofs come with two basic options. Choose an asphalt roof altered for low-slope situations or a polymer-based roofing material. Which low slope commercial roofing material should be used depends on several factors, including the location, anticipated foot traffic, and the owner's ability to maintain the roof.

BUR

Built-up asphalt roofing (BUR) has been around for a while now. Roofs lay several plies of material down much as they would shingles and they layer this material with asphalt. Melted asphalt is applied with a mop before being covered with a cap sheet. The cap sheet includes a reflective coating or mineral surface.

Roofers have been using this material for over 100 years, although the product has changed over time. The changes made have led to BUR being used less frequently today. Not only must the components be assembled on-site, but the roofers must be skilled in using this material. Additional drawbacks come with using this material.

It cannot contract and expand significantly. As a result, it is prone to damage. It is heavy, hard to maintain, and difficult to repair. For this reason, many roofers now turn to modified bitumen products.
